

For this project, I plan to make a solver for the New York Times Spelling Bee game. The game provides users with 7 letters, and the users must spell words with these letters. One of the letters is required to be included in every word. Letters may be repeated. Words must be at least 4 letters long.

Use case: Users can enter a set of letters, and the app will provide a list of words that will count as solutions to the game.

Input: 7 letters, with one of them marked as the required letter to be used in every word.

Output: A list of words of at least length 4 that can be used as solutions to the game with the inputted set of letters.

Use case: Users can view a list of the puzzles they have previously viewed/solved using this database. When the user gets solutions for a particular puzzle, that puzzle will be stored in their history. If they choose to view their history, they will see a list of past puzzle dates and the corresponding letters and required letters for those puzzles.
